**Please find below and/or attached an Office communication concerning this application or proceeding.**

The time period for reply, if any, is set in the attached communication.

### Office Action Summary

**Application No.**

10/068,254

**Applicant(s)**

VALE ET AL.

**Examiner**

KELLY L. JERABEK

**Art Unit**

2622

**Period for Reply** -- The MAILING DATE of this communication appears on the cover sheet with the correspondence address --

A SHORTENED STATUTORY PERIOD FOR REPLY IS SET TO EXPIRE 3 MONTH(S) OR THIRTY (30) DAYS, WHICHEVER IS LONGER, FROM THE MAILING DATE OF THIS COMMUNICATION.

- Extensions of time may be available under the provisions of 37 CFR 1.136(a). In no event, however, may a reply be timely filed after SIX (6) MONTHS from the mailing date of this communication.
- If NO period for reply is specified above, the maximum statutory period will apply and will expire SIX (6) MONTHS from the mailing date of this communication.
- Failure to reply within the set or extended period for reply will, by statute, cause the application to become ABANDONED (35 U.S.C. § 133). Any reply received by the Office later than three months after the mailing date of this communication, even if timely filed, may reduce any earned patent term adjustment. See 37 CFR 1.704(b).

#### Status

- 1) ☒ Responsive to communication(s) filed on 02 June 2008.
- 2a) ☐ This action is **FINAL**. 2b) ☒ This action is non-final.
- 3) ☐ Since this application is in condition for allowance except for formal matters, prosecution as to the merits is closed in accordance with the practice under *Ex parte Quayle*, 1935 C.D. 11, 453 O.G. 213.

#### Disposition of Claims

- 4) ☒ Claim(s) 1-7, 10-16, 18-26, 29 and 30 is/are pending in the application.
- 4a) Of the above claim(s) \_\_\_\_\_ is/are withdrawn from consideration.
- 5) ☐ Claim(s) \_\_\_\_\_ is/are allowed.
- 6) ☒ Claim(s) 1-7, 10-16, 18-26, 29 and 30 is/are rejected.
- 7) ☐ Claim(s) \_\_\_\_\_ is/are objected to.
- 8) ☐ Claim(s) \_\_\_\_\_ are subject to restriction and/or election requirement.

#### Application Papers

- 9) ☐ The specification is objected to by the Examiner.
- 10) ☒ The drawing(s) filed on 02 October 2006 is/are: a) ☒ accepted or b) ☐ objected to by the Examiner.
- Applicant may not request that any objection to the drawing(s) be held in abeyance. See 37 CFR 1.85(a).
- Replacement drawing sheet(s) including the correction is required if the drawing(s) is objected to. See 37 CFR 1.121(d).
- 11) ☐ The oath or declaration is objected to by the Examiner. Note the attached Office Action or form PTO-152.

#### Priority under 35 U.S.C. § 119

- 12) ☐ Acknowledgment is made of a claim for foreign priority under 35 U.S.C. § 119(a)-(d) or (f).
- a) ☐ All b) ☐ Some \* c) ☐ None of:
1. ☐ Certified copies of the priority documents have been received.
  2. ☐ Certified copies of the priority documents have been received in Application No. \_\_\_\_\_.
  3. ☐ Copies of the certified copies of the priority documents have been received in this National Stage application from the International Bureau (PCT Rule 17.2(a)).

\* See the attached detailed Office action for a list of the certified copies not received.

#### Attachment(s)

- 1) ☒ Notice of References Cited (PTO-892)
- 2) ☐ Notice of Draftsperson's Patent Drawing Review (PTO-948)
- 3) ☒ Information Disclosure Statement(s) (PTO/SB/08)  
Paper No(s)/Mail Date \_\_\_\_\_
- 4) ☐ Interview Summary (PTO-413)  
Paper No(s)/Mail Date \_\_\_\_\_
- 5) ☐ Notice of Informal Patent Application
- 6) ☐ Other: \_\_\_\_\_

## **DETAILED ACTION**

### ***Continued Examination Under 37 CFR 1.114***

A request for continued examination under 37 CFR 1.114, including the fee set forth in 37 CFR 1.17(e), was filed in this application after final rejection. Since this application is eligible for continued examination under 37 CFR 1.114, and the fee set forth in 37 CFR 1.17(e) has been timely paid, the finality of the previous Office action has been withdrawn pursuant to 37 CFR 1.114. Applicant's submission filed on 6/2/2008 has been entered.

### ***Response to Arguments***

Applicant's arguments with respect to claims 29-30 have been considered but are moot in view of the new ground(s) of rejection.

Applicant's arguments filed 6/2/2008 have been fully considered but they are not persuasive.

### **Response to Remarks:**

Applicant's arguments regarding claims 1-3 and 6 (Amendment pages 8-9) state that the Sato reference is silent regarding whether dedicated software is necessary on the mobile phone or the server to establish such connections. Therefore, applicants submit that the combination of the Bateman, Sato, Yamada and Terakado references fails to teach or suggest, "automatically establishing a wireless network connection between the data capture device and a remote host device that is capable of communication with said data capture device via the pipeline device, wherein the pipeline device enables communication between the data capture device and the remote host device without installation of dedicated software on the pipeline device or the remote host device for enabling said communication". The Examiner respectfully disagrees. Sato discloses a method of facilitating transfer of information from a data capture device (10) to a remote host device (42,45,46), the method comprising: establishing a connection between the data capture device (10) and a pipeline device (44); establishing a wireless network connection between the data capture device (10) and the remote host device (42,45,46) via the pipeline device (44), wherein the pipeline device (44) enables communication between the data capture device (10) and the remote host device (42,45,46) (col. 4, line 36-col. 5, line 55; figures 1,2). The Sato reference states that where the external communications device/pipeline device (44) is a cellular type portable telephone, the portable telephone (44) is automatically connected to a remote server (42) and is automatically connected to the camera (10) when the camera is placed in communication mode (col. 5, lines 32-55). Sato states that this communication is performed and does not state that dedicated software must

be installed on the cellular type portable telephone (pipeline device 44), therefore it is inherent that the cellular type portable telephone (pipeline device 44) is capable of communicating with the data capture device (camera 10) or the remote host device (remote server 42) without installation of dedicated software on the pipeline device. Therefore, the Examiner maintains that the combination of the Bateman, Sato, Yamada and Terakado references discloses all of the limitations of claim 1.

Applicant's arguments regarding claims 1-3 and 6 (Amendment page 9) state that neither the Bateman reference nor the Sato reference discloses providing a notification that a connection between the data capture device and the pipeline device has been established. The Examiner agrees with this statement, however the Yamada reference discloses this limitation. Yamada discloses in figures 1-3 a camera capable of accepting an auxiliary memory card (MC). The camera includes a liquid crystal display section (30) that displays a plurality of icon marks (46-66) according to the operation modes of the camera (col. 3, lines 60-67). Yamada states that when the memory card (MC) is attached to the camera, icon mark (64) is displayed thus verifying that the connection has been established and the microprocessor (MPU1) instructs microprocessor (MPU2) to perform processing operations (col. 6, line 53 – col. 7, line 10). Thus, it can be seen that Yamada discloses that it is well known in the digital imaging art to provide a notification to the user of a camera when a connection between the camera and a remote device is established. Therefore, the Examiner maintains that

the Yamada reference provides the teaching of providing a notification that a connection between a data capture device and a pipeline device has been established.

Applicant's arguments regarding claims 1-3 and 6 (Amendment pages 9-10) state that the Sato reference fails to teach that the digital camera is preconfigured to establish a connection with a specific remote host device. Therefore, applicants submit that the combination of the Bateman, Sato, Yamada and Terakado references fails to teach or suggest, "wherein said data capture device is preconfigured to establish the wireless network connection with the remote host device via the pipeline device upon establishing the connection with the pipeline device". The Examiner respectfully disagrees. Sato discloses a method of facilitating transfer of information from a data capture device (10) to a remote host device (42,45,46), the method comprising: establishing a connection between the data capture device (10) and a pipeline device (44); establishing a wireless network connection between the data capture device (10) and the remote host device (42,45,46) via the pipeline device (44), wherein the pipeline device (44) enables communication between the data capture device (10) and the remote host device (42,45,46) (col. 4, line 36-col. 5, line 55; figures 1,2). The Sato reference states that where the external communications device/pipeline device (44) is a cellular type portable telephone, the portable telephone (44) is automatically connected to a remote server (42) and is automatically connected to the camera (10) when the camera is placed in communication mode (col. 5, lines 32-55). Sato states that when the user of the camera (10) sets the camera (10) into communication mode,

Art Unit: 2622

the camera (10) establishes a connection with pipeline device (portable telephone 44) and the pipeline device (portable telephone 44) is automatically connected to the nearest server (42) (col. 5, lines 32-55). Thus, it can be seen that Sato discloses that the data capture device (10) is preconfigured (set in communication mode) to establish a wireless network connection with a remote host device (42) via the pipeline device (44) upon establishing a connection with the pipeline device (44). Therefore, the Examiner maintains that the combination of the Bateman, Sato, Yamada and Terakado references discloses all of the limitations of claim 1.

Applicant's arguments regarding claims 1-3 and 6 (Amendment pages 10-11) state that Yamada reference fails to reach or suggest establishing a connection from a data capture device, through a pipeline device, to a remote host. Therefore, Yamada cannot teach providing a notification that a transfer of information from a data capture device, through a pipeline device, to a remote host device is in process. The Examiner respectfully disagrees. The Yamada reference was cited to show that it is well known in the digital imaging art to provide a notification to the user of a camera when a connection between the camera and a remote device is established. The combination of the Bateman and Sato references discloses a method for facilitating transfer of information from a data capture device, through a pipeline device, to a remote host device. However, although the combination of the Bateman and Sato references discloses the above limitations, it fails to specifically disclose that upon connection of the data capture device to the host device through the pipeline device, a notification that

a transfer of information is in process and notification of successful completion of the transfer of information is automatically provided.

Yamada discloses in figures 1-3 a camera capable of accepting an auxiliary memory card (MC). The camera includes a liquid crystal display section (30) that displays a plurality of icon marks (46-66) according to the operation modes of the camera (col. 3, lines 60-67). When the memory card (MC) is attached to the camera, icon mark (64) is displayed thus verifying that the connection has been established and the microprocessor (MPU1) instructs microprocessor (MPU2) to perform processing operations (col. 6, line 53 – col. 7, line 10). When the camera is in the copying mode of copying image data from the main memory (MM) to the memory card (MC), icon mark (62) automatically provides a notification that a transfer of information is in process (col. 4, lines 32-35; col. 9, line 59 – col. 10, line 15). Each time an individual image is transferred and copied the values of icon marks (56, 60) are changed (col. 11, line 59 – col. 12, line 10). Thus, icon marks (56,60) provide notification of successful completion of the transfer of information. Therefore, it would have been obvious for one skilled in the art to have been motivated to automatically provide notification that a transfer of information is in process and automatically provide notification of successful completion of a transfer of information as disclosed by Yamada in the system configured to transfer data between a peripheral device and a host through a pipeline device as disclosed by the combination of Bateman and Sato. Doing so would provide a means for allowing a user of an image capture device to view the transfer status of image data being transferred from the image capture device to a host.

Therefore, the Examiner maintains that the Yamada reference provides the teaching of providing a notification that a connection between a data capture device and a pipeline device has been established and is in process.

Applicant's arguments regarding claims 15, 18, 21-22 and 25 (Amendment pages 11-13) are similar to the arguments above regarding claims 1-3 and 6. Therefore, the arguments above regarding claims 1-3 and 6 also apply to claims 15, 18, 21-22 and 25.

***Claim Rejections - 35 USC § 103***

The following is a quotation of 35 U.S.C. 103(a) which forms the basis for all obviousness rejections set forth in this Office action:

(a) A patent may not be obtained though the invention is not identically disclosed or described as set forth in section 102 of this title, if the differences between the subject matter sought to be patented and the prior art are such that the subject matter as a whole would have been obvious at the time the invention was made to a person having ordinary skill in the art to which said subject matter pertains. Patentability shall not be negated by the manner in which the invention was made.

**Claims 1-3 and 6 are rejected under 35 U.S.C. 103(a) as being unpatentable over Bateman et al. US 2002/0194414 in view of Sato et al. US 7,265,779 in view of Yamada et al. US 6,239,837 and further in view of Terakado et al. US 2002/0001042.**

Re claim 1, Bateman discloses a method facilitating transfer of information from a data capture device (102) to a host device (108,112) (page 2, paragraphs 21-22). Bateman states that the connection between the camera base unit (102,104) and the host (108,112) includes both tethered and wireless connections; where in the wireless case, the base unit (102,104) is capable of wirelessly transmitting to and receiving data from the host (108,112) (page 2, paragraphs 20-21). Therefore, it can be seen that Bateman teaches a wireless network connection between a data capture device (102,104) and a host device (108,112). Bateman further states that upon connection of a data capture device (102) to a host device (108,112) that is capable of communicating with the data capture device (102), automatically verifying that a connection has been established between the data capture device (102) and the host device (page 3, paragraph 28) and automatically initiating an immediate transfer of information from the data capture device (102) (pages 2-3 paragraph 23). However, although the Bateman reference discloses all of the above limitations including a wireless communication between a camera and a remote device it fails to specifically disclose a method of facilitating transfer of information from a data capture device to a remote host device, the method comprising: establishing a connection between the data capture device and a pipeline device; establishing a wireless network connection between the data capture device and the remote host device via the pipeline device, wherein the pipeline device enables communication between the data capture device and the remote host device without installation of dedicated software on the pipeline device or the remote host device for enabling said communication, wherein said data capture device is

preconfigured to establish the wireless network connection with the remote host device via the pipeline device upon establishing the connection with the pipeline device.

Sato discloses a method of facilitating transfer of information from a data capture device (10) to a remote host device (42,45,46), the method comprising: establishing a connection between the data capture device (10) and a pipeline device (44); establishing a wireless network connection between the data capture device (10) and the remote host device (42,45,46) via the pipeline device (44), wherein the pipeline device (44) enables communication between the data capture device (10) and the remote host device (42,45,46) without installation of dedicated software on the pipeline device (44) or the remote host device (42,45,46) for enabling communication (col. 4, line 36-col. 5, line 55; figures 1,2). Sato discloses a method of facilitating transfer of information from a data capture device (10) to a remote host device (42,45,46), the method comprising: establishing a connection between the data capture device (10) and a pipeline device (44); establishing a wireless network connection between the data capture device (10) and the remote host device (42,45,46) via the pipeline device (44), wherein the pipeline device (44) enables communication between the data capture device (10) and the remote host device (42,45,46) (col. 4, line 36-col. 5, line 55; figures 1,2). Sato states that this communication is performed and does not state that dedicated software must be installed on the cellular type portable telephone (pipeline device 44), therefore it is inherent that the cellular type portable telephone (pipeline device 44) is capable of communicating with the data capture device (camera 10) or the remote host device (remote server 42) without installation of dedicated software on the

pipeline device. The Sato reference further states that where the external communications device/pipeline device (44) is a cellular type portable telephone, the portable telephone (44) is automatically connected to a remote server (42) and is automatically connected to the camera (10) when the camera is placed in communication mode (col. 5, lines 32-55). Sato states that when the user of the camera (10) sets the camera (10) into communication mode, the camera (10) establishes a connection with pipeline device (portable telephone 44) and the pipeline device (portable telephone 44) is automatically connected to the nearest server (42) (col. 5, lines 32-55). Thus, it can be seen that Sato discloses that the data capture device (10) is preconfigured (set in communication mode) to establish a wireless network connection with a remote host device (42) via the pipeline device (44) upon establishing a connection with the pipeline device (44). Therefore, it would have been obvious for one skilled in the art to have been motivated to include the teaching of enabling a camera to utilize a pipeline device to communicate wirelessly with remote devices as disclosed by Sato in the camera capable of wirelessly communicating with remote devices disclosed by Bateman. Doing so would provide a means for enabling a camera to communicate with remote devices that are located far away from the camera.

Although the combination of the Bateman and Sato references discloses all of the above limitations the combination fails to specifically state that upon connection of the data capture device to the host device through the pipeline device, notification that a connection between the capture device and the pipeline device has been established,

notification that a transfer of information is in process and notification of successful completion of the transfer of information is automatically provided.

Yamada discloses in figures 1-3 a camera capable of accepting an auxiliary memory card (MC). The camera includes a liquid crystal display section (30) that displays a plurality of icon marks (46-66) according to the operation modes of the camera (col. 3, lines 60-67). When the memory card (MC) is attached to the camera, icon mark (64) is displayed thus verifying that the connection has been established and the microprocessor (MPU1) instructs microprocessor (MPU2) to perform processing operations (col. 6, line 53 – col. 7, line 10). When the camera is in the copying mode of copying image data from the main memory (MM) to the memory card (MC), icon mark (62) automatically provides a notification that a transfer of information is in process (col. 4, lines 32-35; col. 9, line 59 – col. 10, line 15). Each time an individual image is transferred and copied the values of icon marks (56, 60) are changed (col. 11, line 59 – col. 12, line 10). Thus, icon marks (56,60) provide notification of successful completion of the transfer of information. Therefore, it would have been obvious for one skilled in the art to have been motivated to automatically provide notification that the connection between the data capture device and the pipeline device has been established, automatically provide notification that a transfer of information is in process and automatically provide notification of successful completion of a transfer of information as disclosed by Yamada in the system configured to transfer data between a peripheral device and a host as disclosed by the combination of Bateman and Sato. Doing so would provide a means for allowing a user of an image capture device to view the

transfer status of image data being transferred from the image capture device to a host. However, although the combination of the Bateman, Sato and Yamada references discloses all of the above limitations, the combination fails to state that notification of successful completion of a transfer of information is provided by illumination or extinguishing of a light on the data capture device.

Terakado discloses a remote controller (1) that is capable of communicating with multiple electronic devices (3,9,13) (figure 2). Terakado states that CPU (1a) turns on LED (100) to indicate that information is being transferred and the CPU (1a) turns off the LED (100) to indicate the information transfer has finished (page 5, paragraphs 74-84). Thus, it can be seen that it is well known to illuminate or extinguish an LED to notify a user of a device of a transfer state of the device. Therefore, it would have been obvious for one skilled in the art to have been motivated to include an LED to indicate the completion of an information transfer as disclosed by Terakado in the camera system disclosed by the combination of Bateman, Sato and Yamada. Doing so would provide a means for providing an indication that a transfer of information is either in process or has been completed.

Re claims 2 and 3, Terakado states that the notification that the transfer of information is in process is provided by illumination of a light (LED 100) (page 5, paragraph 75).

Re claim 6, when the camera disclosed by Yamada is in the copying mode of copying image data from the main memory (MM) to the memory card (MC), icon mark (62) automatically provides a notification that a transfer of information is in process (col. 4, lines 32-35; col. 9, line 59 – col. 10, line 15). Icon mark (62) is displayed on LCD (30) therefore the icon mark (62) is a notification that a transfer of information is in process that is provided on an LCD (30).

**Claims 4-5, 7 and 10-14 are rejected under 35 U.S.C. 103(a) as being unpatentable over Bateman et al. in view of Sato et al. in view of Yamada in view of Terakado et al. and further in view of Okada US 6,630,954.**

Re claim 4, the combination of the Bateman, Sato, Yamada and Terakado references disclose all of the limitations of claims 1 and 2 above. However, although the Terakado reference discloses an LED (100) for providing a notification of information transfer it fails to state that the LED blinks periodically while the transfer of information is in process.

Okada discloses an image pickup apparatus including an image erasure status notification function. If the image data has already been transferred, a message is provided to the user indicating that the image to be erased has already been transferred to another storing area (col. 2, lines 54-62). The message is provided to the user using either a flickering LED, a display of an LCD, or a sound generation of a buzzer (col. 2,

lines 41-53). Therefore, it would have been obvious for one skilled in the art to have been motivated to include the concept of using a flickering LED or a buzzer for user notification as disclosed by Okada in the system configured to transfer data between a peripheral device and a host as disclosed by the combination of Bateman, Sato, Yamada and Terakado. Doing so would provide a means for flickering an LED or sounding a buzzer in order to provide notifications to a user of a camera (Okada: col. 2, lines 54-62).

Re claim 5, the combination of the Bateman, Sato, Yamada and Terakado references disclose all of the limitations of claims 1 and 2 above. However, although the Terakado reference discloses an LED (100) for providing a notification of information transfer it fails to state that the LED is green.

Okada discloses an image pickup apparatus including an image erasure status notification function. If the image data has already been transferred, a message is provided to the user indicating that the image to be erased has already been transferred to another storing area (col. 2, lines 54-62). The message is provided to the user using either a flickering LED, a display of an LCD, or a sound generation of a buzzer (col. 2, lines 41-53). Additionally, the LED disclosed by Okada is green to confirm that an image has been transferred (col. 2, lines 41-46). Therefore, it would have been obvious for one skilled in the art to have been motivated to include the concept of using an flickering LED or a buzzer for user notification as disclosed by Okada in the system configured to transfer data between a peripheral device and a host as disclosed by the

combination of Bateman, Sato, Yamada and Terakado. Doing so would provide a means for flickering an LED or sounding a buzzer in order to provide notifications to a user of a camera (Okada: col. 2, lines 54-62).

Re claim 7, the combination of the Bateman, Sato, Yamada and Terakado references disclose all of the limitations of claims 1 and 2 above. However, although the Terakado reference discloses an LED (100) for providing a notification of information transfer it fails to state that a notification that the transfer of information is in process is provided by an audio signal.

Okada discloses an image pickup apparatus including an image erasure status notification function. If the image data has already been transferred, a message is provided to the user indicating that the image to be erased has already been transferred to another storing area (col. 2, lines 54-62). The message is provided to the user using either a flickering LED, a display of an LCD, or a sound generation of a buzzer (col. 2, lines 41-53). Therefore, it would have been obvious for one skilled in the art to have been motivated to include the concept of using an flickering LED or a buzzer for user notification as disclosed by Okada in the system configured to transfer data between a peripheral device and a host as disclosed by the combination of Bateman, Sato, Yamada and Terakado. Doing so would provide a means for flickering an LED or sounding a buzzer in order to provide notifications to a user of a camera (Okada: col. 2, lines 54-62).

Re claim 10, the combination of Bateman, Sato, Yamada and Terakado discloses all of the limitations of claims 1 above. Yamada also states the when the capacity of the auxiliary memory is insufficient before the whole image is transferred icon mark (60) indicates the number of uncopied image data (col. 12, lines 11-49). However, the combination of Bateman, Sato, Yamada and Terakado does not specifically disclose an automatic notification of failure if the transfer of information is not successfully completed.

Okada discloses an image pickup apparatus including an image erasure status notification function. If the image data has not been transferred, a message is provided to the user indicating that the image to be erased has not been transferred to another storing area (col. 2, line 63 - col. 3, line 24). The message is provided to the user using either a flickering LED, a display of an LCD, or a sound generation of a buzzer (col. 3, lines 1-10). Therefore, it would have been obvious for one skilled in the art to have been motivated to include the concept of using an LED or a buzzer to notify a user that a transfer of information was not successfully completed as disclosed by Okada in the system configured to transfer data between a peripheral device and a host as disclosed by the combination of Bateman, Sato, Yamada and Terakado. Doing so would provide a means for flickering an LED or sounding a buzzer in order to provide notifications to a user of a camera that an image has not yet been transferred (Okada: col. 3, lines 11-19).

Re claims 11-13, Okada states that a red LED is lit to notify the user that the image to be erased is not transferred (col. 3, lines 1-4).

Re claim 14, Okada states that a message on an LCD is used to notify the user that the image to be erased is not transferred (col. 3, lines 4-8).

**Claims 15, 18, 21-22 and 25 are rejected under 35 U.S.C. 103(a) as being unpatentable over Bateman et al. US 2002/0194414 in view of Sato et al. US 7,265,779 and further in view of Yamada et al. US 6,239,837.**

Re claim 15, Bateman discloses a method facilitating transfer of information from a data capture device (102) to a host device (108,112) (page 2, paragraphs 21-22). Bateman states that the connection between the camera base unit (102,104) and the host (108,112) includes both tethered and wireless connections; where in the wireless case, the base unit (102,104) is capable of wirelessly transmitting to and receiving data from the host (108,112) (page 2, paragraphs 20-21). Therefore, it can be seen that Bateman teaches a wireless network connection between a data capture device (102,104) and a host device (108,112). Bateman further states that upon connection of a data capture device (102) to a host device (108,112) that is capable of communicating with the data capture device (102), automatically verifying that a connection has been established between the data capture device (102) and the host device (page 3,

paragraph 28) and automatically initiating an immediate transfer of information from the data capture device (102) (pages 2-3 paragraph 23). However, although the Bateman reference discloses all of the above limitations including a wireless communication between a camera and a remote device it fails to specifically disclose a method of facilitating transfer of information from a data capture device to a remote host device, the method comprising: establishing a connection between the data capture device and a pipeline device; establishing a wireless network connection between the data capture device and the remote host device via the pipeline device, wherein the pipeline device enables communication between the data capture device and the remote host device without installation of dedicated software on the pipeline device or the remote host device for enabling said communication, wherein said data capture device is preconfigured to establish the wireless network connection with the remote host device via the pipeline device upon establishing the connection with the pipeline device.

Sato discloses a method of facilitating transfer of information from a data capture device (10) to a remote host device (42,45,46), the method comprising: establishing a connection between the data capture device (10) and a pipeline device (44); establishing a wireless network connection between the data capture device (10) and the remote host device (42,45,46) via the pipeline device (44), wherein the pipeline device (44) enables communication between the data capture device (10) and the remote host device (42,45,46) without installation of dedicated software on the pipeline device (44) or the remote host device (42,45,46) for enabling communication (col. 4, line 36-col. 5, line 55; figures 1,2). Sato discloses a method of facilitating transfer of

information from a data capture device (10) to a remote host device (42,45,46), the method comprising: establishing a connection between the data capture device (10) and a pipeline device (44); establishing a wireless network connection between the data capture device (10) and the remote host device (42,45,46) via the pipeline device (44), wherein the pipeline device (44) enables communication between the data capture device (10) and the remote host device (42,45,46) (col. 4, line 36-col. 5, line 55; figures 1,2). Sato states that this communication is performed and does not state that dedicated software must be installed on the cellular type portable telephone (pipeline device 44), therefore it is inherent that the cellular type portable telephone (pipeline device 44) is capable of communicating with the data capture device (camera 10) or the remote host device (remote server 42) without installation of dedicated software on the pipeline device. The Sato reference further states that where the external communications device/pipeline device (44) is a cellular type portable telephone, the portable telephone (44) is automatically connected to a remote server (42) and is automatically connected to the camera (10) when the camera is placed in communication mode (col. 5, lines 32-55). Sato states that when the user of the camera (10) sets the camera (10) into communication mode, the camera (10) establishes a connection with pipeline device (portable telephone 44) and the pipeline device (portable telephone 44) is automatically connected to the nearest server (42) (col. 5, lines 32-55). Thus, it can be seen that Sato discloses that the data capture device (10) is preconfigured (set in communication mode) to establish a wireless network connection with a remote host device (42) via the pipeline device (44) upon

establishing a connection with the pipeline device (44). Therefore, it would have been obvious for one skilled in the art to have been motivated to include the teaching of enabling a camera to utilize a pipeline device to communicate wirelessly with remote devices as disclosed by Sato in the camera capable of wirelessly communicating with remote devices disclosed by Bateman. Doing so would provide a means for enabling a camera to communicate with remote devices that are located far away from the camera.

Although the combination of the Bateman and Sato references discloses all of the above limitations the combination fails to specifically state that upon connection of the data capture device to the host device through the pipeline device, notification that a connection between the capture device and the pipeline device has been established, notification that a transfer of information is in process and notification of successful completion of the transfer of information is automatically provided.

Yamada discloses in figures 1-3 a camera capable of accepting an auxiliary memory card (MC). The camera includes a liquid crystal display section (30) that displays a plurality of icon marks (46-66) according to the operation modes of the camera (col. 3, lines 60-67). When the memory card (MC) is attached to the camera, icon mark (64) is displayed thus verifying that the connection has been established and the microprocessor (MPU1) instructs microprocessor (MPU2) to perform processing operations (col. 6, line 53 – col. 7, line 10). When the camera is in the copying mode of copying image data from the main memory (MM) to the memory card (MC), icon mark (62) automatically provides a notification that a transfer of information is in process (col. 4, lines 32-35; col. 9, line 59 – col. 10, line 15). Each time an individual image is

Art Unit: 2622

transferred and copied the values of icon marks (56, 60) are changed (col. 11, line 59 – col. 12, line 10). Thus, icon marks (56,60) provide notification of successful completion of the transfer of information. Therefore, it would have been obvious for one skilled in the art to have been motivated to automatically provide notification that the connection between the data capture device and the pipeline device has been established, automatically provide notification that a transfer of information is in process and automatically provide notification of successful completion of a transfer of information as disclosed by Yamada in the system configured to transfer data between a peripheral device and a host as disclosed by the combination of Bateman and Sato. Doing so would provide a means for allowing a user of an image capture device to view the transfer status of image data being transferred from the image capture device to a host.

Re claim 18, when the memory card (MC) is attached to the camera, icon mark (64) is displayed on LCD (30) thus verifying that the connection has been established and the microprocessor (MPU1) instructs microprocessor (MPU2) to perform processing operations (col. 6, line 53 – col. 7, line 10).

Re claim 21, when the camera is in the copying mode of copying image data from the main memory (MM) to the memory card (MC), icon mark (62) automatically provides a notification on LCD (30) that a transfer of information is in process (col. 4, lines 32-35; col. 9, line 59 – col. 10, line 15).

Re claims 22 and 25, each time an individual image is transferred and copied the values of icon marks (56, 60) on LCD (30) are changed (col. 11, line 59 – col. 12, line 10). Therefore, icon marks (56,60) provide notification of successful completion of the transfer of information.

**Claims 16, 19-20, 23-24 and 26 are rejected under 35 U.S.C. 103(a) as being unpatentable over Bateman et al. in view of Sato et al. in view of Yamada and further in view of Okada US 6,630,954.**

Re claim 16, the combination of the Bateman, Sato and Yamada references discloses all of the limitations of claim 15 above. However, the notifications provided by Yamada are icon marks that are displayed on an LCD. The combination of Bateman, Sato and Yamada does not specifically state that the notifications are light emitting diodes or audio signals.

Okada discloses an image pickup apparatus including an image erasure status notification function. If the image data has already been transferred, a message is provided to the user indicating that the image to be erased has already been transferred to another storing area (col. 2, lines 54-62). The message is provided to the user using either a flickering LED, a display of an LCD, or a sound generation of a buzzer (col. 2, lines 41-53). Therefore, it would have been obvious for one skilled in the art to have

been motivated to include the concept of using an LED or a buzzer for user notification as disclosed by Okada in the system configured to transfer data between a peripheral device and a host as disclosed by the combination of Bateman, Sato and Yamada. Doing so would provide a means for flickering an LED or sounding a buzzer in order to provide notifications to a user of a camera (Okada: col. 2, lines 54-62).

Re claims 19-20 and 23, the combination of the Bateman, Sato and Yamada references discloses all of the limitations of claim 15 above. However, the notifications provided by Yamada are icon marks that are displayed on an LCD. The combination of Bateman, Sato and Yamada does not specifically state that the notification consists of a blinking light emitting diode.

Okada discloses an image pickup apparatus including an image erasure status notification function. If the image data has already been transferred, a message is provided to the user indicating that the image to be erased has already been transferred to another storing area (col. 2, lines 54-62). The message is provided to the user using either a flickering LED, a display of an LCD, or a sound generation of a buzzer (col. 2, lines 41-53). Therefore, it would have been obvious for one skilled in the art to have been motivated to include the concept of using an LED or a buzzer for user notification as disclosed by Okada in the system configured to transfer data between a peripheral device and a host as disclosed by the combination of Bateman, Sato and Yamada. Doing so would provide a means for flickering an LED or sounding a buzzer in order to provide notifications to a user of a camera (Okada: col. 2, lines 54-62).

Re claim 24, the combination of the Bateman, Sato, Yamada and Okada references discloses all of the limitations of claim 23 above. Yamada uses icon marks (56,60) to provide notification of successful completion of transfer of information but does not specifically state that the notification is provided by extinguishing a light on the data capture device. The Examiner takes **Official Notice** that it is well known in the art to illuminate an LED on a device that is transferring data during the transfer of the data and to turn off the LED when the transfer is completed. Therefore, it would have been obvious for one skilled in the art to have been motivated to provide an LED that is turned off when the transfer of data is completed in place of the icon marks (56,60) for providing visual notification of successful completion of transfer of information.

Re claim 26, the combination of the Bateman, Sato and Yamada references disclose all of the limitations of claims 15 above. Yamada also states the when the capacity of the auxiliary memory is insufficient before the whole image is transferred icon mark (60) indicates the number of uncopied image data (col. 12, lines 11-49). However, the combination of the Bateman, Sato and Yamada references does not specifically disclose an automatic notification of failure if the transfer of information is not successfully completed.

Okada discloses an image pickup apparatus including an image erasure status notification function. If the image data has not been transferred, a message is provided

to the user indicating that the image to be erased has not been transferred to another storing area (col. 2, line 63 - col. 3, line 24). The message is provided to the user using either a flickering LED, a display of an LCD, or a sound generation of a buzzer (col. 3, lines 1-10). Therefore, it would have been obvious for one skilled in the art to have been motivated to include the concept of using an LED or a buzzer to notify a user that a transfer of information was not successfully completed as disclosed by Okada in the system configured to transfer data between a peripheral device and a host as disclosed by the combination of Bateman, Sato and Yamada. Doing so would provide a means for flickering an LED or sounding a buzzer in order to provide notifications to a user of a camera that an image has not yet been transferred (Okada: col. 3, lines 11-19).

**Claim 29 is rejected under 35 U.S.C. 103(a) as being unpatentable over Bateman et al. US 2002/0194414 in view of Yamada et al. US 6,239,837 in view of Terakado et al. US 2002/0001042 and further in view of Takahashi US 2002/0051065.**

Re claim 29, Bateman discloses a method facilitating transfer of information from a data capture device (102) to a host device (108,112) (page 2, paragraphs 21-22). Bateman states that the connection between the camera base unit (102,104) and the host (108,112) includes both tethered and wireless connections; where in the wireless case, the base unit (102,104) is capable of wirelessly transmitting to and receiving data

from the host (108,112) (page 2, paragraphs 20-21). Therefore, it can be seen that Bateman teaches a wireless network connection between a data capture device (102,104) and a host device (108,112). Bateman further states that upon connection of a data capture device (102) to a host device (108,112) that is capable of communicating with the data capture device (102), automatically verifying that a connection has been established between the data capture device (102) and the host device (page 3, paragraph 28) and automatically initiating an immediate transfer of information from the data capture device (102) (pages 2-3 paragraph 23). However, although the Bateman reference discloses all of the above limitations it fails to specifically state that upon connection of the data capture device and to the host device notification that a transfer of information is in process and notification of successful completion of the transfer of information is automatically provided.

Yamada discloses in figures 1-3 a camera capable of accepting an auxiliary memory card (MC). The camera includes a liquid crystal display section (30) that displays a plurality of icon marks (46-66) according to the operation modes of the camera (col. 3, lines 60-67). When the memory card (MC) is attached to the camera, icon mark (64) is displayed thus verifying that the connection has been established and the microprocessor (MPU1) instructs microprocessor (MPU2) to perform processing operations (col. 6, line 53 – col. 7, line 10). When the camera is in the copying mode of copying image data from the main memory (MM) to the memory card (MC), icon mark (62) automatically provides a notification that a transfer of information is in process (col. 4, lines 32-35; col. 9, line 59 – col. 10, line 15). Each time an individual image is

transferred and copied the values of icon marks (56, 60) are changed (col. 11, line 59 – col. 12, line 10). Thus, icon marks (56,60) provide notification of successful completion of the transfer of information. Therefore, it would have been obvious for one skilled in the art to have been motivated to automatically provide notification that a transfer of information is in process and automatically provide notification of successful completion of a transfer of information as disclosed by Yamada in the system configured to transfer data between a peripheral device and a host as disclosed by Bateman. Doing so would provide a means for allowing a user of an image capture device to view the transfer status of image data being transferred from the image capture device to a host. However, although the combination of the Bateman and Yamada references discloses all of the above limitations, the combination fails to state that notification of successful completion of a transfer of information is provided by illumination or extinguishing of a light on the data capture device.

Terakado discloses a remote controller (1) that is capable of communicating with multiple electronic devices (3,9,13) (figure 2). Terakado states that CPU (1a) turns on LED (100) to indicate that information is being transferred and the CPU (1a) turns off the LED (100) to indicate the information transfer has finished (page 5, paragraphs 74-84). Thus, it can be seen that it is well known to illuminate or extinguish an LED to notify a user of a device of a transfer state of the device. Therefore, it would have been obvious for one skilled in the art to have been motivated to include an LED to indicate the completion of an information transfer as disclosed by Terakado in the camera system disclosed by the combination of Bateman and Yamada. Doing so would provide

a means for providing an indication that a transfer of information is either in process or has been completed. However, although the combination of the Bateman, Yamada and Terakado references discloses all of the above limitations, however the combination fails to disclose automatically deleting said information from said data capture device upon successful completion of said transfer.

Takahashi discloses a digital camera that is capable of transferring image data to remote devices. Takahashi states that when transfer of the image data from the transfer buffer memory (131) of the digital camera (1) to the personal computer (2) is completed, the MPU (11) automatically deletes the transferred image data in the transfer buffer memory (131) (page 13, paragraph 152). Therefore, it would have been obvious for one skilled in the art to have been motivated to include the teaching of automatically deleting image data in a digital camera when the image data is successfully transferred to a remote device as disclosed by Takahashi in the camera system disclosed by the combination of the Bateman, Yamada and Terakado references. Doing so would provide a means for deleting image data that has been successfully transferred to remote devices in order to free up image storage space in a digital camera.

**Claim 30 is rejected under 35 U.S.C. 103(a) as being unpatentable over Bateman et al. US 2002/0194414 in view of Yamada et al. US 6,239,837 in view of in view of Terakado et al. US 2002/0001042 in view of Takahashi US 2002/0051065 and further in view of Jackel et al. US 2003/0133015.**

Re claim 30, the combination of the Bateman, Yamada, Terakado and Takahashi references discloses all of the limitations of claim 29 above. However, although the combination of the references discloses a camera capable of wirelessly communicating with remote devices none of the references state that the wireless network connection is a wireless internet connection.

Jackel discloses a web-connected interactive digital camera. The camera (10) disclosed by Jackel is capable of communicating with remote devices via a wireless internet connection (page 2, paragraph 19). Therefore, it would have been obvious for one skilled in the art to have been motivated to include the teaching of enabling a camera to communicate wirelessly with remote devices via a wireless internet connection as disclosed by Jackel in the camera capable of wirelessly communicating with remote devices disclosed by the combination of Bateman, Yamada, Terakado and Takahashi. Doing so would provide a means for enabling a camera to communicate with remote devices that are located far away from the camera.
